

Tags and taxonomies

A taxonomy groups pages by shared metadata such as tags, categories, authors, or topics. You can build one without special configuration: add an array to each page's `<website-metadata>`, then filter the entries returned by `calepin.pages()`.

For example, documentation pages on this site declare tags alongside their other metadata:

```
#metadata((
  title: "Pages",
  tags: ("websites", "metadata"),
)) <website-metadata>
```

Create a regular page for the taxonomy index. The following generic function collects the values of any array-valued metadata field, then lists the matching pages under each value:

```
#import "./calepin/calepin.typ" as calepin
#show: calepin.document

#let taxonomy(field) = {
  let pages = calepin.pages()
  .filter(page => page.meta.at(field, default: ()) != ())
  let terms = pages
  .map(page => page.meta.at(field))
  .flatten()
  .dedup()
  .sorted(key: term => lower(term))

  for term in terms {
    heading(term, level: 2)
    for page in pages.filter(
      page => term in page.meta.at(field)
    ) [
      - #link(page.href)[#page.title]
    ]
  }
}

#taxonomy("tags")
```

This approach keeps taxonomies ordinary Typst code. You control the page's route and presentation, and the same function works for fields such as categories or authors. Add sorting, counts, summaries, or pagination using the usual Typst array methods.
