

PDF templates

layouts/pdf.typ is the Typst-side layout used by PDF and SVG notebook outputs.

```
themes/my-theme/  
layouts/  
pdf.typ
```

Before Typst runs, Calepin renders this file with MiniJinja, the same engine used for HTML layouts (see Templating), so the output is still valid Typst source. The file uses a .typ extension because it renders to Typst, even though it is a MiniJinja template.

Inside the layout, place notebook content with `document.body`:

```
#set page(  
  paper: "us-letter",  
  margin: (x: 1in, y: 0.85in),  
  numbering: "1",  
)  
  
#set text(font: "Libertinus Serif", size: 10.5pt)  
  
{{ document.body }}
```

Useful layouts/pdf.typ values:

- theme: local theme directory name
- target: notebook
- document.path: .typ input path relative to workspace
- document.dir: input directory relative to workspace
- document.stem: input filename without .typ
- document.body: notebook body, injected as a #include
- document.meta: values from #metadata(...) <website-metadata>
- params: CLI parameter map
- vars: custom values from [vars] in calepin.toml, the same map HTML templates receive

If `document.body` is not referenced, Calepin appends the notebook body after the rendered layout.

`theme = "typst"` disables notebook-specific theming, and `extends = "typst"` creates a local theme with no inherited Calepin base. Use an empty layouts/pdf.typ for a minimal pass-through layout. notebook.typ.jinja and paged.typ.jinja are not supported.
