

# Navigation and listings

## Sidebar

Navigation can be explicit:

```
[sidebar]

[[sidebar.section]]
title = "Guide"

    [[sidebar.section.item]]
    path = "index.typ"
    label = "Home"

    [[sidebar.section.item]]
    path = "usage.typ"
    label = "Usage"
```

Each section can contain any number of `item` entries. An item can point to one file with `path`:

```
[[sidebar.section.item]]
path = "install.typ"
label = "Install"
```

An item can also include files with a simple glob:

```
[[sidebar.section.item]]
glob = "guide/*.typ"
```

If no sidebar is configured, *Calepin* builds navigation from `.typ` files in the source directory. Hidden paths are skipped by default. Set `show_hidden = true` under `[sidebar]` to include hidden paths in manual navigation file discovery.

## Page titles

Navigation labels are resolved in this order:

1. the label configured on the sidebar item
2. the title entry of the page's `<website-metadata>` metadata
3. the file name, with `-` and `_` replaced by spaces

To set a page title in the document itself:

```
#metadata((title: "Getting started")) <website-metadata>
```

Page metadata is extracted while the page is preprocessed, from the same staged source used for rendering. Package imports such as `@preview/calepin` are already rewritten at that point, so metadata works in pages that do not compile standalone.

## Page listings

Pages can list other pages of the website, for example to build a blog index. During a website build, every page can call `calepin.pages()`:

```
#import "@preview/calepin:0.0.1" as calepin

#for post in calepin.pages()
```

```

.filter(p => p.path.starts-with("blog/"))
.sorted(key: p => p.meta.at("date", default: ""))
.rev() [
- #link(post.href)[#post.title] (#post.meta.at("date", default: ""))
]

```

Each entry is a dictionary:

- path: the source file, relative to the website source directory (blog/first.typ)
- href: a link to the page, already relative to the current page
- title: the resolved display title, matching the navigation
- pdf: a link to the page's PDF, or none when no PDF is rendered
- meta: the page's <website-metadata> dictionary, verbatim

*Calepin* interprets only the title, pdf, and hidden keys of page metadata. Everything else in meta (dates, tags, authors, categories) is yours to define and filter on. Outside a website build, `calepin.pages()` returns an empty array, so pages compile standalone.

Blog posts usually should not appear in the sidebar. Include them in the build with a sidebar glob, then mark each post:

```

#metadata((title: "First Post", date: "2026-06-01", hidden: true)) <website-
metadata>

```

`hidden: true` removes a page from the navigation while keeping it built, listed in `calepin.pages()`, and present in `sitemap.xml`.

When any page's metadata changes, *Calepin* rebuilds the whole site during watch so that listing pages never go stale.
