

PDF

layouts/pdf.typ is the Typst-side layout used by PDF and SVG notebook outputs.

```
themes/my-theme/  
  layouts/  
    pdf.typ
```

Before Typst runs, Calepin renders this file with MiniJinja, the same engine used for HTML layouts (see Templating), so the output is still valid Typst source. The file uses a .typ extension because it renders to Typst, even though it is a MiniJinja template.

Inside the layout, place notebook content with `doc.body`:

```
#set page(  
  paper: "us-letter",  
  margin: (x: 1in, y: 0.85in),  
  numbering: "1",  
)  
  
#set text(font: "Libertinus Serif", size: 10.5pt)  
  
{{ doc.body }}
```

Useful layouts/pdf.typ values:

- theme: local theme directory name
- target: paged
- doc.path: .typ input path relative to workspace
- doc.dir: input directory relative to workspace
- doc.stem: input filename without .typ
- doc.title: document title, or an empty string
- doc.body: notebook body, injected as a #include
- doc.meta: values from #metadata(...) <website-metadata>
- store: the completed document store from [store], calepin.store.set(), successful store-set chunks, and CLI --set store.<name>=... overrides

doc.body must be included explicitly if you want the notebook body in the rendered output.

theme = "typst" disables notebook-specific theming, and extends = "typst" creates a local theme with no inherited Calepin base. Use an empty layouts/pdf.typ for a minimal pass-through layout.

Code blocks and chunk output are styled through labeled elements, so a layout restyles them with ordinary show rules. See Styling chunks.
